12 **Introduction** 5
13 6

14 The introduction of computing methodologies into the humanities has brought 14
15 about significant changes both in the scope of humanities research and in the 15
16 way that research is to be carried out. These new methodologies have offered 16
17 the chance to ask questions that have never been asked before and to give 17
18 new and more satisfying answers to questions previously asked. Importantly, 18
19 interdisciplinarity as a scientific approach to the study of complex issues has gained 19
20 more and more importance, and technological advances, together with the need 20
21 for interdisciplinary studies, have made it increasingly essential to do research 21
22 in collaboration. The development of humanities computing has been noticeably 22
23 enhanced by the various emerging forms of virtual collaboration offered by the 23
24 use of the internet. To name a few pioneering initiatives without trying to give a 24
25 comprehensive overview, HUMBUL, which started in 1985, offered catalogued 25
26 and reviewed websites relevant to the humanities at a time when today's search 26
27 engines did not even exist. Nearly ten years on, the book *The Whole Internet* 27
28 (Krol, 1992) could still be printed on a few hundred pages. The discussion group 28
29 *Humanist* started in 1987 and is probably one of the oldest existing international 29
30 online seminars still in existence and flourishing today. And of course the 30
31 humanistic disciplines themselves have been enhanced by the emergence of easier 31
32 and faster ways for colleagues to collaborate across the boundaries of subjects, 32
33 institutions and countries. 33

34 The emergence of international organizations for humanities computing attests 34
35 to the rapid growth in communities in the field: the Association for Literary and 35
36 Linguistic Computing (ALLC), founded in 1973, and the Association for Computing 36
37 in the Humanities (ACH), founded in 1978, initially served the communities 37
38 mainly in Europe and North America, respectively, and the new publications— 38
39 *Literary and Linguistic Computing* and *Computing and the Humanities*—which 39
40 they established opened new forums for scholarly work in the field throughout 40
41 the world. Community building and support has been continuous ever since: the 41
42

43 1 This article was partly supported by the joint Hungary–EU Grant No. TÁMOP 43
44 4.2.2-08/1-2008-0009. 44

1 emergence of the Alliance of Digital Humanities Organizations (ADHO) in 2007 1
 2 as the umbrella organization of ALLC and ACH is a natural consequence of the 2
 3 growth and globalization of computing in the humanities. Other organizations are 3
 4 encouraged to join ADHO, and the Society for Digital Humanities/Société pour 4
 5 l'étude des médias interactifs (SDH-SEMI, founded in 1986 as the Consortium for 5
 6 Computers in the Humanities/Consortium pour ordinateurs en sciences humaines) 6
 7 has recently done so. ADHO hopes to promote the emergence of new, online 7
 8 publications in the field, such as *Digital Humanities Quarterly (DHQ)*, which 8
 9 began publication in 2007. 9

10 In general, the emergence and development of interdisciplinary research in 10
 11 the humanities has been accompanied and/or supported by the emergence and 11
 12 development of various forms of collaboration in the past decades. The two 12
 13 seem to go hand in hand, one facilitating the other and offering new perspectives 13
 14 both for academic studies and research activities. What seems to be shared by 14
 15 many of these efforts is preference for virtual, online forms of collaboration. 15
 16 In what follows, we will give examples of virtual collaboration as it appears 16
 17 in today's practice, ranging from academic education to academic research to 17
 18 R&D activities. This attempts to show how digital humanities can contribute to 18
 19 advances in other research fields and also, vice versa, how it can benefit from 19
 20 traditionally "remote" disciplines. 20

21 The activities and thoughts associated with and inspired by the idea of 21
 22 collaborative work described in these pages are strongly influenced by the 22
 23 intellectual spirit I had the chance to encounter through the many years of my 23
 24 acquaintance with Professor Harold Short. One main message that has remained 24
 25 for me as a guiding light ever since is that we have to turn to our fellow colleagues 25
 26 with a keen interest in their work, offer and incorporate new ideas, and seek 26
 27 further and ever more productive forms of interdisciplinary research. The 27
 28 international community of digital humanities has always been a "safe haven" for 28
 29 me where I could experience a warmly welcoming and stimulating, but critical, 29
 30 intellectual environment for the development and testing of innovative ideas on 30
 31 the crossroads of exciting, mutually complementary as well as competing fields. 31
 32 It has been motivating for me to see a new discipline emerge and to understand 32
 33 that this new discipline will leave enough room for our original fields (linguistics 33
 34 in my case) while creating a "virtual cloud" of collaboration within and across 34
 35 individual disciplines. I can only hope to be able to contribute to handing over 35
 36 this spirit to the next generation. 36

37 37
 38 38

39 **Collaboration in Virtual Centers for "Real" Education** 39 40 40

41 There is a perception in a number of universities in Europe that humanities 41
 42 faculties are currently facing troubled times, only partly shared by some other 42
 43 academic disciplines. The decrease of state funding has noticeably affected the 43
 44 humanities, while the number of students enrolled in many traditional majors 44

1 is stagnating or even gradually falling. The cut in state funds has affected the 1
2 humanities especially badly because—in contrast to the sciences—external 2
3 funds are much harder to generate. Whereas in the sciences demands for 3
4 technological advances obviously generate additional funds, the traditional 4
5 approach of the humanities, not being technology- or even “consumer”-oriented, 5
6 results in the humanities disciplines becoming less competitive in the race for 6
7 funds. In addition, the decrease of enrolments is ominous: fewer students choose 7
8 traditional humanities disciplines, mainly due to market pressure—they wish to 8
9 have a degree which opens their way to a decent career and prestige. Regardless 9
10 of sound argumentation based on well-tested traditional values, entering the 10
11 competition both for funds and for students with old perceptions seems not too 11
12 promising. However, studying present-day and prospective future demands may 12
13 offer a solution: the introduction of computing in humanities education and 13
14 research may have the effect that, similarly to the introduction of computing in 14
15 several other disciplines, the use of computing methodologies might enhance 15
16 traditional studies in the humanities and result both in new answers and new 16
17 discoveries. This is the route some leading universities in Europe and America 17
18 have chosen. They introduced computing in various aspects of the humanities, 18
19 thus enhancing and further widening the scope of humanities computing for 19
20 education, research and application development. One of the institutional 20
21 forerunners in humanities computing was King’s College London, where a 21
22 new department was set up to pursue the goal of institutional development of 22
23 humanities computing. The emergence of digital humanities (DH) as a new 23
24 discipline, as we know it now, was the result of continuous development in many 24
25 areas of humanities computing, both in education and research. The idea was 25
26 gradually developed that DH as an academic offering could find its place among 26
27 disciplines in the humanities and even offer a contribution to disciplines beyond 27
28 the humanities as well. 28

29 When we at the University of Debrecen were first contemplating introducing 29
30 humanities computing into the Faculty of Humanities, we hoped that by doing 30
31 so we could give fresh momentum to humanities education and humanities 31
32 research. We expected that, as a result, we could build a community that would 32
33 bring about a substantial renewal of the practice of traditional humanities 33
34 and create a new, more comprehensive “space” for humanities education and 34
35 research. We discovered, however, that to start a new program with no history 35
36 in the country at all is no easy matter. It is first necessary to establish DH as 36
37 a recognized academic discipline and then get the accreditation to begin a 37
38 program in a particular institution. Both requirements need an institutional 38
39 background that we, at the outset, equally lacked. Normally, the traditional way 39
40 of running an academic program is to associate it with a single (rarely more) 40
41 academic discipline, but we soon realized that DH cannot be associated with a 41
42 single “traditional” humanities discipline. Therefore our endeavor was twofold: 42
43 establish a single organizational unit for DH and then a single discipline 43
44 associated with it. 44

1 Initially, we were aware that there were individual academics teaching a subject 1
 2 that in one way or another included some applied computational methodology. 2
 3 There was, however, no collaboration or any other professional relationship 3
 4 among the individual teachers. Thus, we decided as the first step to establish a 4
 5 community that would later on undertake the education as well. 5

6 In order to build the institutional background necessary for any hope of success 6
 7 in national accreditation, we needed some traditional form of organization that 7
 8 would submit the proposal for accreditation, either a department or a research 8
 9 center. Since DH was a new discipline not belonging to the profile of any existing 9
 10 department or research center, we decided to establish a new, virtual Center for 10
 11 Digital Humanities. It needed to be virtual because it would rely on existing 11
 12 teaching positions; these positions would remain in their respective departments 12
 13 and offer an extra service to run courses in humanities computing as well. 13

14 The Center for Digital Humanities set out its program: it planned to elaborate 14
 15 a proposal for an MA in Digital Humanities, secure the teaching staff, and offer 15
 16 additional activities. The proposal was essentially based on two sources: similar DH 16
 17 programs elsewhere for reference, consultations, and possible co-operation; and 17
 18 the availability and interest of the potential teaching staff. The two specializations 18
 19 offered by the program would reflect two classes of broader interest: *cultural* 19
 20 *heritage preservation* and *language technology*. The disciplines that are thus 20
 21 represented are quite numerous, enabling students to enter the program with a BA 21
 22 in, among other subjects, modern and classical languages and literatures, history 22
 23 and ethnology. The disciplines taught in the MA program range from classical 23
 24 humanities and information science to music, even to related issues in architecture 24
 25 and the sciences. 25

26 We cannot leave this story without documenting its outcome. In the first round, 26
 27 our submission for recognizing DH as an independent discipline was unsuccessful. 27
 28 For the second submission, we had to convince the respective bodies that: (a) what 28
 29 we offer is not information science proper, but a humanities-oriented teaching 29
 30 and research scenario with a strong reliance on approaches, methodologies, and 30
 31 techniques of IT; and (b) what information science, especially some exams, such 31
 32 as ECDL, offers does not—contrary to some superficial assumptions—cover those 32
 33 fields that are the characteristics of DH: the integration of humanities and some 33
 34 other disciplines with information science from a particular, unique perspective. 34
 35 Based on strong arguments supported by spectacular achievements in the wider 35
 36 field of digital humanities, DH was finally recognized as an independent academic 36
 37 discipline at the masters level. Shortly after that, the University of Debrecen 37
 38 received national accreditation to also run the program. Following a successful 38
 39 series of lectures in 2010 as an introductory course, with the enrollment of more 39
 40 than two dozen students with a wide variety of subjects as their primary humanities 40
 41 background, we look forward with enthusiasm to launching the first full-fledged 41
 42 program in 2011. Beyond its own advancement, DH will also serve as an example 42
 43 in Hungary of how interdisciplinary co-operation across traditional academic 43
 44 boundaries can contribute to the modernization of higher education. 44

1 Virtual Space: The Academic Benefit of Professional Collaboration

2
3 Today's technology allows us to disseminate knowledge to a much wider audience
4 than is possible in a traditional classroom setting. To reach as wide an audience as
5 possible is especially important in the case of a new discipline such as DH.
6 This is what led us to make our participation at the annual European
7 Researchers' Night, an international event, through videoconferencing. In the
8 last three consecutive years our hub in Debrecen has connected participants from
9 Debrecen, Budapest, Oulu and Dublin via cyberspace. As in an ordinary event,
10 we had "plenary talks" and "round table discussions" alike. The audience from all
11 sites could enjoy the event and be part of it by asking questions and reflecting upon
12 any issues arising. A videostream was also broadcast to enable "unregistered"
13 viewers to participate. The impact of these two events on the audience was quite
14 measurable: being mostly students, they received the talks and discussions with
15 much enthusiasm. Even some term papers originated from them as a reflection
16 on the scientific merit of these events, suggesting that DH has found a fruitful
17 ground to further grow and develop. The impact on students of these events is also
18 measurable by the fact that last year's was organized and run by PhD students,
19 suggesting that DH will have its future among the younger generation.
20 In addition to these European Researchers' Night events, the same technology
21 has also been tested and utilized in further educational activities within the
22 framework of our Culture and Technology Seminar Series. The series were jointly
23 designed by the universities of Debrecen, Leipzig, Oulu, and King's College.
24 Later Glasgow, Bologna, and Dublin also joined in our effort to bring the major
25 ideas of DH closer to undergraduates in the respective universities. Students of
26 various disciplines across the continent were connected weekly by the central idea
27 as well as the technology. Professors from the respective universities (E. Burr, D.
28 Buzzetti, L. Hunyadi, W. McCarty, M. Moss, L.L. Opas-Hänninen, and others)
29 gave inspiring talks on their research, all focusing on a particular aspect of digital
30 humanities, ranging from linguistics to literature, history, computer science and
31 engineering. Later, as interest grew, calls for participation were also extended to
32 PhD students. We had exciting and highly motivating presentations by graduate
33 students from Bologna, Debrecen, and Dublin, three universities located far away
34 from each other but connected in the virtual space by a common interest in DH.
35 Already the fact that regular scientific meetings in such a virtual space, under the
36 umbrella of digital humanities, was made possible shows that DH as a discipline
37 has found its place in higher education.
38 The idea that culture and technology could organically meet, sharing the
39 approach of DH, was further developed in Leipzig where the first Summer
40 Schools in Culture and Technology were held in the summers of 2009 and 2010.
41 There are further plans as well: based on the success of seminars run by doctoral
42 students, we intend to offer a virtual conference for young scientists in DH, to be
43 organized simultaneously at various university sites in Europe and broadcast to the
44 participating institutions and possibly beyond. We hope that such a conference will

1 become yet another means of scientific motivation for those young people who 1
 2 are engaged in any aspect of DH and are interested in developing collaboration 2
 3 without borders. This is how the inter- and multidisciplinary concept of DH 3
 4 equally inspires the “virtual” and the “real.” 4

5 5

6 6

7 **The Benefit of Professional Collaboration in Virtual Space for Research and 7**
 8 **Development 8**

9 9

10 Digital humanities is, by definition, inter- and multidisciplinary. Being part of 10
 11 the DH community, one has a strong sense of the benefits of crossing traditional 11
 12 academic boundaries in order to collaborate with respective partners from other 12
 13 disciplines in order to “arrive home,” that is, to give answers to questions often 13
 14 proving too complex for one’s single primary discipline. We can see the benefits 14
 15 of such collaboration in at least three areas: (a) at the institutional, organizational 15
 16 level; (b) in activities of dissemination; and (c) in running individual projects. 16
 17 Below, I will suggest some concrete examples of these benefits. 17

18 (a) At the institutional, organizational level, we must give credit to a significant 18
 19 event with far-reaching consequences for the future of DH, originally initiated and 19
 20 gradually pursued by Harold Short and John Unsworth, backed by their respective 20
 21 organizations: the “merger” of ALLC and ACH under the umbrella of ADHO. 21
 22 Originally, ALLC and ACH used to function on a semi-geographical basis; by 22
 23 the establishment of ADHO (Alliance of Digital Humanities Organizations: 23
 24 <www.digitalhumanities.org/>) in 2005, the DH community has come of age by 24
 25 offering global collaboration and expandability, while at the same time preserving 25
 26 the “local” focuses of the constituting organizations. Going global means that, 26
 27 based on previous successful large-scale projects and both geographically and 27
 28 professionally wide scope actions, it has now become possible to institutionalize 28
 29 the achievements and concentrate our academic, human, and material resources to 29
 30 accomplish even further reaching goals. The first impact at the organizational level 30
 31 was the joining in 2007 of SDH-SEMI, the Canadian organization for DH, a move 31
 32 that simply accomplished a professionally supported natural process. Recently, 32
 33 this movement towards globalization is perceived more and more strongly with 33
 34 regard to Japan: the establishment of ADHO gave significant impetus to strengthen 34
 35 and further enhance the presence of DH in that country, with the possibility of 35
 36 establishing a regional chapter some time in the future. It is also expected that the 36
 37 increasingly global reach of DH through ADHO will result in further academic 37
 38 and organizational advances in other parts of the world as well. 38

39 (b) Activities of dissemination are very important in the development of an 39
 40 ever growing community, through making available new advances and sharing 40
 41 best practice in particular fields. Several seminars and other similar events have 41
 42 been initiated or run by the constituting organizations of ADHO in many parts of 42
 43 the world. I will only give one example here, that of a conference and seminar 43
 44 organized by the West Bengal University of Technology, Kolkata in 2007, where 44

1 experts from ALLC were invited to participate. This conference dealt with the 1
2 issue of digitization of a vast number of Indic languages, languages that either 2
3 did not have at that time any encoding system or, on the contrary, had more 3
4 than one but none of them appropriate for standard machine representation and 4
5 analysis. The participation of delegates from ALLC was judged to be very useful 5
6 in that, step by step, they were guided through actual and accomplished projects 6
7 of digitization as possible examples of the use of standard methodologies. The list 7
8 of local participants included a wide range of professions, from linguistics to IT 8
9 to engineering and even nuclear physics, showing that these professionals deeply 9
10 understood the needs of their country in the preservation of objects of their cultural 10
11 heritage. Regardless of their academic orientation, they were ready to contribute to 11
12 this magnificent goal by starting from the very basics and moving steadily towards 12
13 accomplishment. ALLC was proud to be a contributing part of this—in a sense— 13
14 historic moment. 14

15 (c) The essential strength of inter- and multidisciplinary approaches is clearly 15
16 shown in joint projects requiring the contribution of DH (by itself multidisciplinary) 16
17 to the accomplishment of tasks involving further disciplines beyond DH. Below, 17
18 we will give an account of some leading ideas behind a fairly complex project 18
19 involving traditional humanities, information science, and engineering, with 19
20 computational linguistics playing a significant role. 20

21 The project HuComTech (“The Theoretical Foundations of Human–Computer 21
22 Interactions”): <http://hucomtech.unideb.hu/hucomtech>) at the University of 22
23 Debrecen is based on the general observation that man–machine communication 23
24 systems usually lack that “appeal” of naturalness which makes such an interaction 24
25 easy and straightforward for the human participant. The reason is not just the fact 25
26 that computer graphics are still in the phase of development (on the contrary, 26
27 many games or even movies can now be made to appear realistic) or speech 27
28 recognition systems are still restricted to a special or specialized vocabulary, but 28
29 that we do not yet know enough about human–human communication in general. 29
30 The underlying idea is that, if we know how to formally represent the structure 30
31 of a given human–human interaction, we can build computer systems that will 31
32 “behave” in a similar fashion. But the major problem is that, being dependent on 32
33 many individual and in cases never repeated factors (profile, ontology, background 33
34 knowledge on the one hand, and given psychological, cultural, moral, and so on, 34
35 settings on the other), human–human interaction seems to be hard to represent in 35
36 a regular form. The aim of the project, then, is to learn the regularities of human– 36
37 human interactions based on type scenarios and respective ontologies, separate 37
38 these regularities from their context-dependent individual characteristics, and 38
39 finally build and interpret a corresponding structure for the given interaction. 39
40 This task requires the collaboration of many people from various disciplines, and 40
41 the project thus involves computer scientists, engineers, computational linguists, 41
42 specialists in communication, as well as psychologists. The task is inspiring and 42
43 at the same time challenging for all. The novelty of research is mainly represented 43
44 by its special interdisciplinary nature and the way in which it contributes to the 44

1 completion of the research program: it is its cross-disciplinary DH approach 1
2 that unites the often seemingly incompatible counterparts. The major issue, as 2
3 mentioned above, is that of the formal representation of human communication. 3
4 Although several theories exist for communication, most of them miss the criteria 4
5 of formal description necessary for implementation by the computer. Our task, 5
6 then, is to search for and identify those building blocks of communication that, in 6
7 an orderly fashion, contribute to what we can tell the computer as structure. It is the 7
8 computational aspect of DH that leads us in the search for implementable structure 8
9 and that does not let us go astray under the influence of certain functional features 9
10 inherent in any communication, but that go beyond the scope of a technologically 10
11 implementable human–computer interaction system. 11

12 Accordingly, the focus of the project is to propose a model inspired at the 12
13 crossroads of the humanities, engineering, and information science, and to validate 13
14 this model in a practical, working implementation. Supported by approaches 14
15 aiming at unveiling the formal basic structure of communication and also at 15
16 the model-based technological implementations of an arbitrary communicative 16
17 event (cf. Polanyi, 1988, 2004; Jurafsky, 2004; Thione et al., 2004a, 2004b), but 17
18 extending the scope to multimodality and bidirectionality, our model itself is 18
19 generative (cf. Hunyadi, 2011): it inherits its approach from theoretical linguistics 19
20 (the latter originally inspired by the needs of computational linguistics for language 20
21 technology). The approach is modular, a significant property equally important and 21
22 manageable for theoretical linguistics and technology. Namely, the complexity of 22
23 the issue of understanding the basic underlying structure of communication and 23
24 implementing it within technology can be reduced and, consequently, relatively 24
25 conveniently handled by subdividing the flow of communication into a number 25
26 of self-contained but structurally interrelated modules for the description and 26
27 generation of appropriate and specific internal relations. In our model, these 27
28 modules are assumed to be responsible for (a) the generation of the formal skeleton 28
29 of all possible communication events, (b) the functional extension of the formal 29
30 basis of a given event, and (c) the pragmatic extension of the functionally already 30
31 extended, rich formal basis. This latter module contains the interface between the 31
32 verbal (and, from a technological point of view, informal) description of an event 32
33 and its formal technological implementation. All this is done in a unified manner: 33
34 each module consists of a finite set of primitives only specific to the given module 34
35 and a finite set of rules of derivation to derive the set of all possible structures 35
36 within that given module. Modules are connected by applying the same unifying 36
37 principles and rules to them within a structural hierarchy. The big challenge is how 37
38 to map non-formal, practically verbal descriptions of events of communication 38
39 onto formal, parametric data, the latter being the only possible input relevant to 39
40 technology. This is where our approach is thought to offer a strong theoretical 40
41 contribution to the problem. Applying to our model the theory of fuzzy systems 41
42 to capture linguistic descriptions of certain cognitive concepts (cf. Zadeh, 1965; 42
43 Bunt and Black, 2000), we map linguistic variables onto technological parameters 43
44 44

1 in order to handle the two, conceptually apparently very distant, fields of human 1
 2 communication and technology in a single unified system. 2

3 In addition, a further benefit of applying a (humanities-based) generative 3
 4 model to the technology of human-machine interaction is that this model is 4
 5 then bidirectional: it equally models analysis and synthesis, two aspects of 5
 6 communication that virtually happen at the same time but that are usually 6
 7 implemented as two independent and (at least partly) incompatible models. Instead 7
 8 of building separate systems for analysis and synthesis using principally different 8
 9 models, our generative model allows for capturing the relevant aspects of human- 9
 10 human communication as they exist in unity in our own behavior. Even though 10
 11 the task is definitely highly complex, we believe that an attempt to technologically 11
 12 implement at least a restricted subset of communicative relations can serve as a 12
 13 means of validation for the model and its application. 13

14 The complexity of the issues described above suggests that this project can 14
 15 only be carried out in strong co-operation by a number of disciplines. There are 15
 16 many challenges: linguists, engineers, and IT people have radically different 16
 17 conceptual and working methodologies and cultures. We believe that DH that is 17
 18 inter- and multidisciplinary by itself can effectively contribute to the successful 18
 19 establishment of synergy between these groups that are professionally distant but 19
 20 closely related by the definition of the final goal. 20

21 Our virtual Center for Digital Humanities, which has already proved to 21
 22 be successful in making a proposal for the academic program MA in Digital 22
 23 Humanities and which has led further academic activities in virtual space, plays a 23
 24 leading role in this technological project, with the hope that the complex approach 24
 25 of DH will bring this project to successful completion. 25

26 26
 27 27

28 **Multidisciplinary Collaboration in a Virtual Lab** 28
 29 29

30 With significant advances in computing and the use of the internet, it has been 30
 31 made possible to share one and the same physical infrastructure among a number 31
 32 of researchers and research communities, both for individual projects that are 32
 33 connected by way of the use of the same infrastructure and for joint complex tasks. 33
 34 I will present here our current effort to build such a shared physical and virtual 34
 35 research infrastructure, where traditional disciplines of the humanities reach out to 35
 36 and become an integral part of engineering application development. 36

37 As a logical continuation of the HuComTech project mentioned in the 37
 38 previous section, we at the University of Debrecen are in the process of creating a 38
 39 cognitive robotic lab that is: (a) real (physical) in the sense that it is based on a real 39
 40 technological implementation of a primary lab, with all the necessary components 40
 41 like testing space, robots, external sensors, and a complex computing system; and 41
 42 (b) virtual in the sense that we can network into this system a number of “stripped 42
 43 down,” secondary labs which lack the robots but which each has a testing space 43
 44 and is equipped with the necessary external sensors and the appropriate computing 44

1 system. These two kinds of labs are integrated into a single research space using the 1
 2 VIRCA (Virtual Collaboration Arena; cf. <www.virca.hu/>) framework. There are 2
 3 at least two far-reaching benefits of this research setting: (a) each of the secondary, 3
 4 robotless labs can carry out experiments with the robot of the distant primary lab; 4
 5 (b) our labs (either the primary or the secondary) can also be integrated into a 5
 6 larger network of similar labs running the same protocol. As a consequence, it is 6
 7 not only the case that we can use the infrastructure of other distant labs, but we 7
 8 also have the opportunity to invite remote projects to join us and carry out joint 8
 9 research and experiments with and within our project. 9

10 What is the role and interest of humanities and digital humanities in building 10
 11 the above network of real and virtual labs, if the setting seems to be so technical 11
 12 and technology oriented? We learn something significant from engineering and the 12
 13 application of computing methodologies: it can be said that the humanities is strong 13
 14 in building theories such that their validation is usually done by testing their logical 14
 15 consistency. On the other hand, engineering and computing are also necessarily 15
 16 supported by theories, but the nature of their disciplines requires validation by 16
 17 testing them against their physical implementation. Second, whereas findings in, 17
 18 among others, physics or chemistry are verified in real-world tests and experiments, 18
 19 humanities will also have a significant contribution to engineering and especially 19
 20 robotics only if any appropriate theory aimed at engineering development is 20
 21 exposed to testing through and within technology. It is especially true of a theory of 21
 22 communication aimed at cognitive robotics, where any theory has to be tested against 22
 23 the “behavior” of the given robot. In this way a humanities theory can be verified, 23
 24 refined, or rejected as a result of exposure and testing against its technological, 24
 25 robotic implementation. The network of real and virtual cognitive robotic behavior 25
 26 with humans will be able to remotely manipulate the behavior of robots and observe 26
 27 their response, and, ultimately, test the validity of a given theory of human behavior. 27

28 We are aware that the use of a network of real and virtual labs as described 28
 29 above reaches beyond the scope of humanities and even digital humanities, but we 29
 30 also believe that the establishment of such a research environment is very much in 30
 31 line with the general purpose of DH: we need to include in humanities research the 31
 32 power and possibilities of computing in order: (a) to offer a more complete answer 32
 33 to some traditional issues in humanities; and (b) to reach out to multidisciplinary 33
 34 research where we believe our knowledge and methodologies can contribute to the 34
 35 understanding and implementation of more complex issues, that are traditionally 35
 36 non-specific to humanities. Time will show if this direction that we are taking now 36
 37 by building an infrastructure of real and virtual labs will indeed yield the results we 37
 38 are envisaging at present. 38

41 **Summary** 41

42 42

43 The purpose of this chapter has been to show through some concrete examples that 43
 44 humanities research has come a long way since the introduction of computational 44

1 methodologies, to develop into a new discipline called digital humanities. The new 1
 2 technologies adopted from computing have made it possible to introduce novel 2
 3 scientific perspectives by facilitating the emergence of further forms of collaboration 3
 4 among scientists. Inter- and multidisciplinary research has become a “must” to solve 4
 5 certain emerging new issues, giving rise to virtual research collaboration as well. 5
 6 Research, academic education, and technological advances go hand in hand while 6
 7 transforming the whole long-established landscape of humanities, leading it into the 7
 8 digital era which promises so much. Pioneering institutions and organizations, as 8
 9 well as newly emerging ones, lead this march, with the indispensable participation 9
 10 and co-operation of a rapidly growing number of single individuals. 10
